Administrative Notes

- Midterm 1
 - 50 minutes, in class, October 12
 - I won't be there, but Alex will
 - Chapter 1, Appendix A, Chapter 2.1-2.3
 - Good test taking strategy
 - One page crib sheet
 - Use both sides
 - Produce it however you like
 - Hand it in with your exam

Last Time

- Technology scaling \Rightarrow bigger branch predictors!
- Branch Prediction Schemes
 - 2-bit predictor—local history
 - Correlating predictor—global history
 - Tournament predictor—both!

Today

- Dynamic Scheduling
 - Chapter 2.4

Why of Dynamic Scheduling?

- Hardware rearranges instructions to reduce stalls
 - Maintaining exception behavior and data flow
- Handles cases compilers can't
 - Undecidable dependencies, e.g., memory references
 - Does $100(R4) = 20(R6)$?
 - Unpredictable delays, e.g. cache misses
- It simplifies the compiler
 - Code compiled for one pipeline can run efficiently on another
- Supports hardware speculation (Chapter 2.6)
 - Extends dynamic scheduling to expose additional ILP

The Idea

- Allow instructions behind stall to proceed:

```
DIVD  F0, F2, F4
```

```
ADDD  F10, F0, F8
```

```
SUBD  F12, F8, F14
```

- Enables **out-of-order execution**
and allows **out-of-order completion**
 - Recall: what does this imply for exceptions?

Two stage issue

- Simple pipeline
 - Instruction Decode (ID) stage to checks for hazards
- Dynamic scheduling: split ID into two stages
 - *Dispatch*—Decode instructions and check for structural hazards
 - *Issue*—Stall on data hazards, read operands when they are ready, send instructions to FUs
- In-order dispatch
 - All instructions are dispatched in program order
 - Instructions can then bypass each other during issue
⇒ out of order execution!

Tomasulo's Algorithm (TA)

- For IBM 360/91 (before caches!)
- Goal: high performance without special compilers
 - Small number of floating point registers (four in the 360)
 - Opportunity for compiler scheduling was limited
- Key idea: dynamic hazard detection and elimination
 - Track availability of instruction operands (RAW)
 - Rename registers in HW (WAR and WAW)
- Why Study a 1966 Computer?
 - The descendants of this have flourished!
 - Alpha 21264, HP 8000, MIPS 10000, Pentium III, PowerPC 604, ...

Register renaming in TA

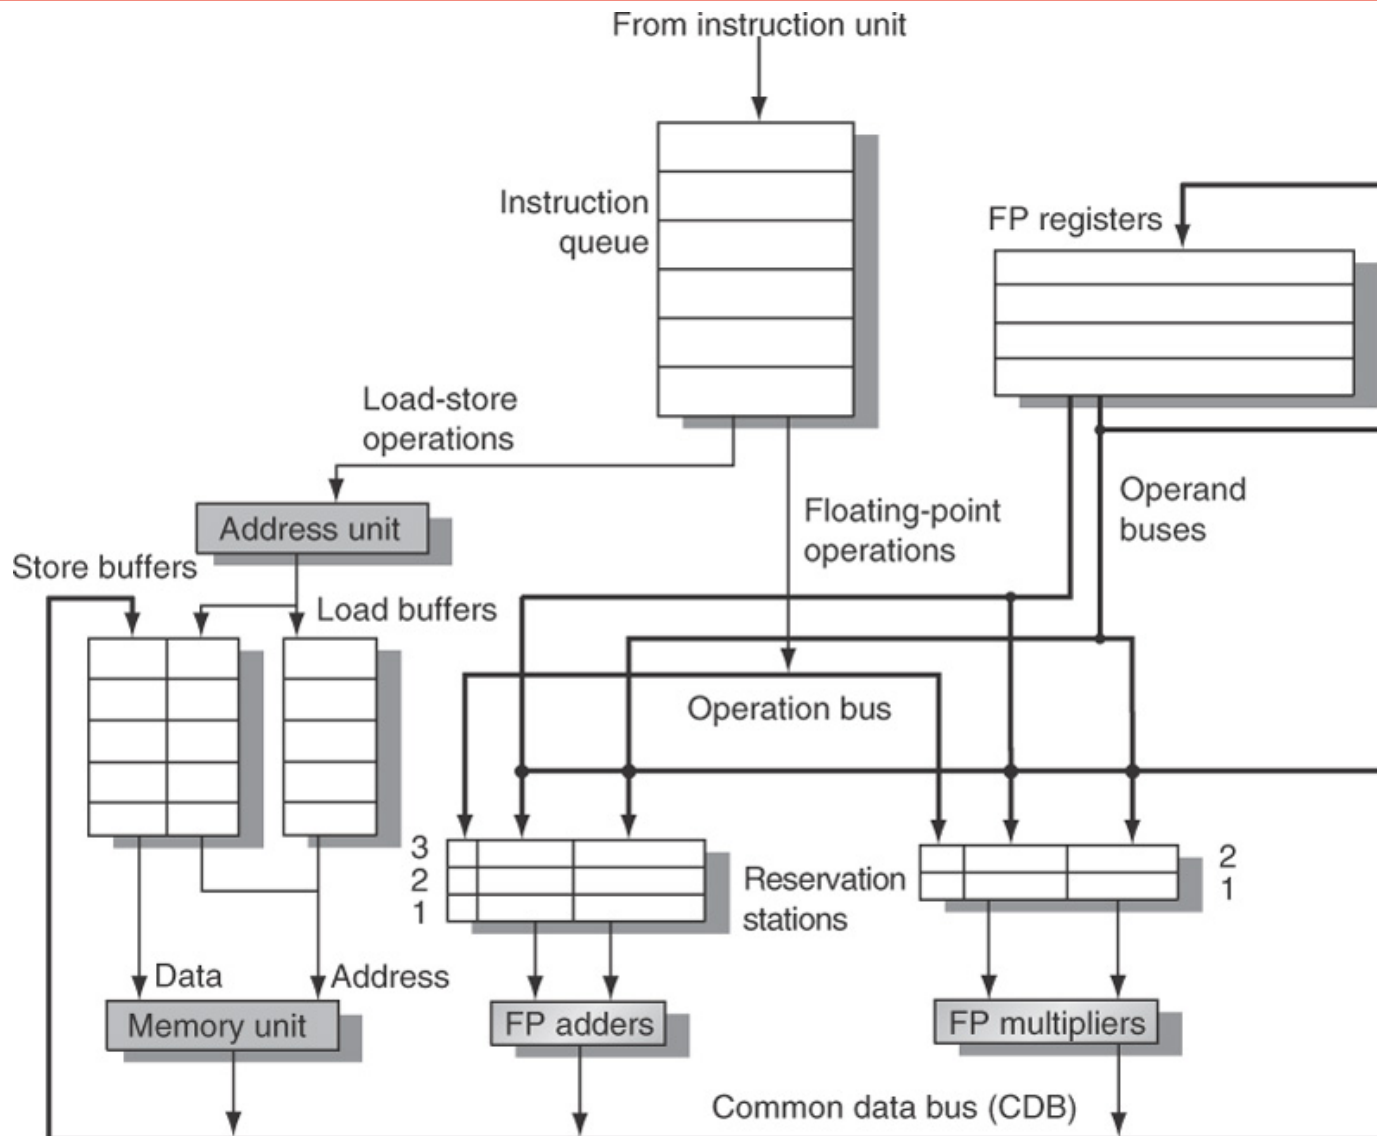

- WAR and WAW hazards

DIVD	F0, F2, F4	DIVD	F0, F2, F4
ADDD	F6, F0, F8	ADDD	S, F0, F8
SD	F6, 0 (R1)	SD	S, 0 (R1)
SUBD	F8, F10, F14	SUBD	T, F10, F14
MULD	F6, F10, F8	MULD	F6, F10, T

- Renaming using Reservation Stations (RS)

- Dispatch instructions to an RS entry: new dst name!
- Get operands as early as possible
- Track which other RS entries produce needed results

MIPS FP using Tomasulo's Algorithm

Three Stages of Execution

1. Issue—get instruction from FP Op Queue
 - When there's a free RS (no structural hazard), issue instruction and send operands (renames registers)
2. Execute—operate on operands (EX)
 - When both operands ready, execute;
if not ready, watch Common Data Bus for results
3. Write Result—finish execution (WB)
 - Write on Common Data Bus to all waiting units;
mark reservation station available

Load and Store Execution

- Loads and stores require two-step execution
- Load and store issue
 - Compute the effective address
 - Issue to the load/store buffer
- Load and store execution
 - Load: execute as the memory unit becomes available
 - Store: have to wait for data, too

Operation and Data Movement

- Operation bus: data + destination
- Common data bus (CDB): data + source
 - Broadcasts 64 bits of data + 4 bits of FU source addr
 - Write if matches expected FU (produces result)
- CDB implements forwarding and bypassing
 - Results transmitted from one FU to another
 - Adds one cycle of latency between producing and consuming instructions: results available in WB only

Tomasulo Example

- Schedule the following code

L.D F6, 34 (R2)

L.D F2, 45 (R3)

MUL.D F0, F2, F4

SUB.D F8, F2, F6

DIV.D F10, F0, F6

ADD.D F6, F8, F2

- Latencies: ADD 2, MULT 10, DIV 40

- Just waiting for Mult2 (DIVD) to complete

Faster than light computation (skip a couple of cycles)

- Once again: In-order issue, out-of-order execution and out-of-order completion.

The same code with static scheduling

- In-order issue, in-order execution and completion

```
L.D      F6, 34 (R2)
L.D      F2, 45 (R3)
        1x stall
MUL.D    F0, F2, F4
SUB.D    F8, F2, F6
        9x stall
DIV.D    F10, F0, F6
ADD.D    F6, F8, F2
        39x stall
```

- Latencies: LD 1, ADD 2, MULT 10, DIV 40
- Total 58 cycles (55 cycles above + MEM + 2WB)

Drawbacks of Tomasulo's Algorithm

- Complexity
 - Large amount of hardware
 - Each RS contains an associative buffer
 - Many associative stores to buffers at high speed
 - Complex control logic
- Performance limited by Common Data Bus
 - Each CDB must go to multiple functional units
⇒ high capacitance, high wiring density
 - Number of functional units that can complete per cycle limited to one!
 - Multiple CDBs ⇒ more FU logic for parallel stores
- Imprecise interrupts!
 - We will address this later
